Protocol for the Examination of Specimens from Patients with Hepatocellular Carcinoma

Cholangiocarcinoma, mixed hepatocellular-cholangiocarcinoma, and hepatoblastoma are not included.

Based on AJCC/UICC TNM, 7th edition
Protocol web posting date: October 2009

Procedure
• Hepatic Resection, Partial or Complete

The College does not permit reproduction of any substantial portion of these protocols without its written authorization. The College hereby authorizes use of these protocols by physicians and other health care providers in reporting on surgical specimens, in teaching, and in carrying out medical research for nonprofit purposes. This authorization does not extend to reproduction or other use of any substantial portion of these protocols for commercial purposes without the written consent of the College.

The CAP also authorizes physicians and other health care practitioners to make modified versions of the Protocols solely for their individual use in reporting on surgical specimens for individual patients, teaching, and carrying out medical research for non-profit purposes.

The CAP further authorizes the following uses by physicians and other health care practitioners, in reporting on surgical specimens for individual patients, in teaching, and in carrying out medical research for non-profit purposes: (1) Dictation from the original or modified protocols for the purposes of creating a text-based patient record on paper, or in a word processing document; (2) Copying from the original or modified protocols into a text-based patient record on paper, or in a word processing document; (3) The use of a computerized system for items (1) and (2), provided that the Protocol data is stored intact as a single text-based document, and is not stored as multiple discrete data fields.

Other than uses (1), (2), and (3) above, the CAP does not authorize any use of the Protocols in electronic medical records systems, pathology informatics systems, cancer registry computer systems, computerized databases, mappings between coding works, or any computerized system without a written license from CAP. Applications for such a license should be addressed to the SNOMED Terminology Solutions division of the CAP.

Any public dissemination of the original or modified Protocols is prohibited without a written license from the CAP.

The College offers these protocols to assist pathologists in providing clinically useful and relevant information when reporting results of surgical specimen examinations of surgical specimens. The College regards the reporting elements in the “Surgical Pathology Cancer Case Summary (Checklist)” portion of the protocols as essential elements of the pathology report. However, the manner in which these elements are reported is at the discretion of each specific pathologist, taking into account clinician preferences, institutional policies, and individual practice.

The College developed these protocols as an educational tool to assist pathologists in the useful reporting of relevant information. It did not issue the protocols for use in litigation, reimbursement, or other contexts. Nevertheless, the College recognizes that the protocols might be used by hospitals, attorneys, payers, and others. Indeed, effective January 1, 2004, the Commission on Cancer of the American College of Surgeons mandated the use of the checklist elements of the protocols as part of its Cancer Program Standards for Approved Cancer Programs. Therefore, it becomes even more important for pathologists to familiarize themselves with these documents. At the same time, the College cautions that use of the protocols other than for their intended educational purpose may involve additional considerations that are beyond the scope of this document.

The inclusion of a product name or service in a CAP publication should not be construed as an endorsement of such product or service, nor is failure to include the name of a product or service to be construed as disapproval.

Summary of Changes
No changes have been made since the October 2009 release.
Surgical Pathology Cancer Case Summary (Checklist)

Protocol web posting date: October 2009

HEPATOCELLULAR CARCINOMA: Hepatic Resection (Note A)

Select a single response unless otherwise indicated.

Specimen (select all that apply)
___Liver
___Gallbladder
___Other (specify): ____________________________
___Not specified

Procedure (select all that apply) (Note B)
___Wedge resection
___Partial hepatectomy
*___Major hepatectomy (3 segments or more)
*___Minor hepatectomy (less than 3 segments)
___Total hepatectomy
___Other (specify): ____________________________
___Not specified

Tumor Size
Greatest dimension: ___ cm
*Additional dimensions: ___ x ___ cm
___Cannot be determined (see Comment)

Tumor Focality (Note B)
___Solitary (specify location): ____________________________
___Multiple (specify location): ____________________________

Histologic Type (Note C)
___Hepatocellular carcinoma
___Fibrolamellar hepatocellular carcinoma
___Undifferentiated carcinoma
___Other (specify): ____________________________
___Carcinoma, type cannot be determined

Histologic Grade (Note D)
___Not applicable
___GX: Cannot be assessed
___GI: Well differentiated
___GII: Moderately differentiated
___GIII: Poorly differentiated
___GIV: Undifferentiated/anaplastic
___Other (specify): ____________________________

* Data elements with asterisks are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.
Tumor Extension (select all that apply)
___ Tumor confined to liver
___ Tumor involves a major branch of the portal vein
___ Tumor involves 1 or more hepatic vein(s)
___ Tumor involves visceral peritoneum
___ Tumor directly invades gallbladder
___ Tumor directly invades other adjacent organs (specify): ______________________________

Margins (select all that apply) (Note E)

Parenchymal Margin
___ Cannot be assessed
___ Uninvolved by invasive carcinoma
   Distance of invasive carcinoma from closest margin: ___ mm
   Specify margin: ______________________________
___ Involved by invasive carcinoma

Other Margin
Specify margin: ______________________________
___ Cannot be assessed
___ Uninvolved by invasive carcinoma
___ Involved by invasive carcinoma

Lymph-Vascular Invasion (Note F)

Macroscopic Venous (Large Vessel) Invasion (V)
___ Not identified
___ Present
___ Indeterminate

Microscopic (Small Vessel) Invasion (L)
___ Not identified
___ Present
___ Indeterminate

*Perineural Invasion
* ___ Not identified
* ___ Present
* ___ Indeterminate

Pathologic Staging (pTNM) (Note G)

TNM Descriptors (required only if applicable) (select all that apply)
___ m (multiple primary tumors)
___ r (recurrent)
___ y (post-treatment)

* Data elements with asterisks are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.
Primary Tumor (pT)
___ pTX: Cannot be assessed
___ pT0: No evidence of primary tumor
___ pT1: Solitary tumor without vascular invasion
___ pT2: Solitary tumor with vascular invasion or multiple tumors none more than 5 cm
___ pT3a: Multiple tumors more than 5 cm
___ pT3b: Single tumor or multiple tumors of any size involving a major branch of the portal vein or hepatic veins
___ pT4: Tumor(s) with direct invasion of adjacent organs other than the gallbladder or with perforation of visceral peritoneum

Regional Lymph Nodes (pN)
___ pNX: Cannot be assessed
___ pN0: No regional lymph node metastasis
___ pN1: Regional lymph node metastasis
Specify: Number examined: ____
Number involved: ____

Distant Metastasis (pM)
___ Not applicable
___ pM1: Distant metastasis
   *Specify site(s), if known: ____________________________

*Additional Pathologic Findings (select all that apply) (Note H)
*Fibrosis score:
   * ____ Cirrhosis/severe fibrosis (Ishak score 5-6) (F1)
   * ____ None to moderate fibrosis (Ishak score 0-4) (F2)

* ____ Hepatocellular dysplasia
   * ____ Low-grade dysplastic nodule
   * ____ High-grade dysplastic nodule
* ____ Steatosis
* ____ Iron overload
* ____ Chronic hepatitis (specify etiology): ________________________________
* ____ Other (specify): ________________________________
* ____ None identified

*Ancillary Studies
*Specify: ________________________________

* Data elements with asterisks are not required. However, these elements may be clinically important but are not yet validated or regularly used in patient management.
*Clinical History (select all that apply) (Note I)
*___ Cirrhosis
*___ Hepatitis C infection
*___ Hepatitis B infection
*___ Alcoholic liver disease
*___ Obesity
*___ Hereditary hemochromatosis
*___ Other (specify): ______________________________
*___ Not known

*Comment(s)
Explanatory Notes

A. Application
This protocol applies only to hepatic resection specimens containing hepatocellular carcinoma. Carcinomas of the intrahepatic bile ducts (cholangiocarcinomas) are now staged using a separate TNM system.

B. Tumor Location, Focality and Histologic Sampling
The segmental anatomy of the liver is shown in Figure 1. Although these divisions are useful for anatomic localization of tumors, it is often not possible to assign segmental location on resection specimens, and such information is best provided by the surgeon.

Sections should be prepared from each major tumor nodule, with representative sampling of smaller nodules, if macroscopically different in appearance. Cirrhotic nodules appreciably larger than the surrounding background liver should also be sampled, because such nodules may harbor dysplastic changes. For purposes of staging, satellite nodules, multifocal primary hepatocellular carcinomas, and intrahepatic metastases are not distinguished and are considered multiple tumors.

C. Histologic Type
The protocol recommends the following modified classification of the World Health Organization (WHO). In the United States, almost 70% of the primary malignant tumors of the liver are hepatocellular carcinomas.

WHO Classification of Carcinomas of the Liver (Modified)
Hepatocellular carcinoma
   Variant: Fibrolamellar hepatocellular carcinoma
Undifferentiated carcinoma
Multiple histologic architectural patterns, such as trabecular, solid, and pseudoglandular patterns, are often found in the same tumor in hepatocellular carcinoma, but only the fibrolamellar variant appears to have prognostic significance, although the relatively longer survival for this variant may relate to its occurrence in younger patients and in the noncirrhotic liver. Tumors that contain areas of both fibrolamellar carcinoma and typical hepatocellular carcinoma should not be classified as fibrolamellar carcinoma; this term should be reserved for those tumors showing only the fibrolamellar pattern.

D. Histologic Grade

Grading of Hepatocellular Carcinoma

The grading system of Edmondson and Steiner is recommended for hepatocellular carcinomas by this protocol and by the AJCC Cancer Staging Manual, 7th edition. However, the use of other grading systems is not precluded.

Grade I
Reserved for hepatocellular carcinomas where the difference between the tumor cells and hyperplastic liver cells is so minor that a diagnosis of carcinoma rests upon the demonstration of more aggressive growths in other parts of the neoplasm. Because grade is assigned based upon the highest grade present, in effect grade I is rarely if ever used for overall tumor grade designation.

Grade II
Cells show marked resemblance to normal hepatic cells. Nuclei are larger and more hyperchromatic than in normal cells. Cytoplasm is abundant and acidophilic. Cell borders are sharp and clear cut. Acini are frequent and variable in size. Lumina are often filled with bile or protein precipitate.

Grade III
Nuclei are larger and more hyperchromatic than in grade II cells. The nuclei occupy a relatively greater proportion of the cell (high nuclear to cytoplasmic [N:C] ratio). Cytoplasm is granular and acidophilic, but less so than grade II tumors. Acini are less frequent and not as often filled with bile or protein precipitate. More single-cell growth in vascular channels is seen than in grade II.

Grade IV
Nuclei are intensely hyperchromatic. Nuclei occupy a high percentage of the cell. Cytoplasm is variable in amount, often scanty. Cytoplasm contains fewer granules. The growth pattern is medullary in character, trabeculae difficult to find, and cell masses seem to lie loosely without cohesion in vascular channels. Only rare acini are seen. Spindle cell areas have been seen in some tumors. Short plump cell forms, resembling “small cell” carcinoma of the lung, are seen in some grade IV tumors.

The pathologist should specify the grading system used. The higher the grade, the less the resemblance of the tumor to “normal” liver, and the more obvious its morphologic features are to malignant growth.

Histologic grade has been shown to have a relationship to tumor size, tumor presentation, and metastatic rate. Low histologic grade has been shown to be predictive of disease-free survival, but not of overall actuarial survival.
E. Margins
The evaluation of margins for total or partial hepatectomy specimens depends on the method and extent of resection. It is recommended that the surgeon be consulted to determine the critical foci within the margins that require microscopic evaluation. The transection margin of a partial hepatectomy may be large, rendering it impractical for complete examination. In this setting, grossly positive margins should be microscopically confirmed and documented. If the margins are grossly free of tumor, judicious sampling of the cut surface in the region closest to the nearest identified tumor nodule is indicated. In selected cases, adequate random sampling of the cut surface may be sufficient. If the neoplasm is found near the surgical margin, the distance from the margin should be reported. For multiple tumors, the distance from the nearest tumor should be reported.

F. Venous and Small Vessel Invasion
Vascular invasion includes gross as well as microscopic invasion of vessels. Macroscopic venous invasion is generally accompanied by microscopic invasion, but it is less commonly found than microscopic invasion alone (15% versus 43%). Both are associated with lower survival post-resection. Larger tumors (greater than 5 cm) or multiple tumors are more likely to exhibit vascular invasion than single small lesions.

G. TNM and Anatomic Stage/Prognostic Groupings
The TNM staging system of the American Joint Committee on Cancer (AJCC) and the International Union Against Cancer (UICC) applies to hepatocellular carcinomas. It does not apply to hepatic sarcomas or to metastatic tumors of the liver. The T classification depends on the number of tumor nodules, the size of the largest nodule, and the presence or absence of blood vessel invasion. The TNM classification does not discriminate between multiple independent primary tumors or intrahepatic metastasis from a single primary hepatic carcinoma. Vascular invasion includes either the gross or the histologic involvement of vessels. Portal vein invasion is an important adverse prognostic factor and should be reported.

According to AJCC/UICC convention, the designation “T” refers to a primary tumor that has not been previously treated. The symbol “p” refers to the pathologic classification of the TNM, as opposed to the clinical classification, and is based on gross and microscopic examination. pT entails a resection of the primary tumor or biopsy adequate to evaluate the highest pT category, pN entails removal of nodes adequate to validate lymph node metastasis, and pM implies microscopic examination of distant lesions. Clinical classification (cTNM) is usually carried out by the referring physician before treatment during initial evaluation of the patient or when pathologic classification is not possible.

Pathologic staging is usually performed after surgical resection of the primary tumor. Pathologic staging depends on pathologic documentation of the anatomic extent of disease, whether or not the primary tumor has been completely removed. If a biopsied tumor is not resected for any reason (eg, when technically infeasible) and if the highest T and N categories or the M1 category of the tumor can be confirmed microscopically, the criteria for pathologic classification and staging have been satisfied without total removal of the primary cancer.
TNM Descriptors
For identification of special cases of TNM or pTNM classifications, the “m” suffix and “y,” “r,” and “a” prefixes are used. Although they do not affect the stage grouping, they indicate cases needing separate analysis.

The “m” suffix indicates the presence of multiple primary tumors in a single site and is recorded in parentheses: pT(m)NM.

The “y” prefix indicates those cases in which classification is performed during or after initial multimodality therapy (ie, neoadjuvant chemotherapy, radiation therapy, or both chemotherapy and radiation therapy). The cTNM or pTNM category is identified by a “y” prefix. The ycTNM or ypTNM categorizes the extent of tumor actually present at the time of that examination. The “y” categorization is not an estimate of tumor before multimodality therapy (ie, before initiation of neoadjuvant therapy).

The “r” prefix indicates a recurrent tumor when staged after a documented disease-free interval and is identified by the “r” prefix: rTNM.

The “a” prefix designates the stage determined at autopsy: aTNM.

Stage IVB any T any N M1

Lymph Nodes
Histologic examination of a regional lymphadenectomy specimen usually involves examination of 3 or more lymph nodes. The regional lymph nodes of the hepatic region include the hilar, hepatoduodenal ligament, inferior phrenic, and caval lymph nodes. Nodal involvement of lymph nodes distal to the hilar, hepatoduodenal ligament, and caval lymph nodes are considered as indicative of distant metastasis (pM1).

H. Additional Pathologic Findings

Fibrosis
Cirrhosis or severe fibrosis (Ishak score 5 or 6) should be specifically reported because it has an adverse effect on outcome. The scoring system described by Ishak is recommended by the AJCC Cancer Staging Manual, 7th edition, and by this protocol.

### Dysplastic Nodules

Reporting of dysplastic changes in cirrhotic nodules is optional in specimens with hepatocellular carcinoma, but it may be helpful in assessing risk for second primary tumors in patients undergoing partial hepatectomy. Dysplastic nodules are generally considered important precursors to hepatocellular carcinoma. The criteria outlined by the International Working Party are recommended,\(^2\) although difficulties in assessment of these lesions and variation in interobserver agreement are recognized.

In brief, dysplastic nodules are nodular lesions displaying some degree of cytologic or architectural atypia but lacking definitive histologic features of malignancy. Dysplastic nodules are further subdivided into low and high grades, depending on the degree of histologic abnormality.

\(^\text{a}\) Characterized by smaller cell size, a greater nuclear to cytoplasmic ratio, cytoplasmic basophilia, and denser cellularity in comparison with the surrounding extranodular hepatocytes.

Specific types of underlying disease, such as viral hepatitis or hemochromatosis, should be separately evaluated and graded, if appropriate.

---

### I. Clinical History

Hepatocellular carcinoma (HCC) is highly linked to chronic liver disease, in particular chronic hepatitis B (HBV) and C (HCV) infection and alcoholic liver disease. Overall, 50%
to 55% of cases of HCC worldwide are attributed to HBV and 25% to 30% to HCV.\textsuperscript{12} but virtually any condition associated with chronic hepatic injury and especially with cirrhosis may predispose to HCC. The annual risk of HCC developing in a cirrhotic liver is estimated at 1% to 6%, with the risk generally highest in the context of chronic viral infection and hereditary hemochromatosis. Nonalcoholic fatty liver disease is increasingly recognized as a risk factor for HCC.\textsuperscript{13}
